Age Threshold for the Association of Periodontitis with Ischemic Stroke

Introduction

Periodontitis is discussed to be an independent risk factor for systemic disease such as cardio- and cerebrovascular disease, COPD, Diabetes mellitus and adverse pregnancy outcomes. However, the nature of the association remains still unclear.

Objectives

Aim of the study was to investigate the influence of the age of a study population on the association between periodontitis and ischemic stroke.

Material and Methods

Subjects and Methods

303 consecutive patients with acute ischemic stroke (T) and 300 representative population controls (C) adjusted for age, gender, ethnicity, time of examination and area of residence.

Subjects were thoroughly examined - both clinically and radiographically - for the presence of periodontitis (number of teeth, caries, restorations, GI, PI, probing pocket depths, clinical attachment levels, furcation defects).

All individuals were interviewed by trained interviewers using a standardized questionnaire that focused on previous diseases, vascular and periodontal risk factors, including smoking, drinking habits and nutrition, social history, previous and present medication, and a detailed assessment of dental care.

Data management and analysis

Statistical Software Package SAS

Double data entry

Data consistency check

Descriptive statistics

Multiple logistic regression analysis

All analyses were done for participants older than 60 and up to 60 years of age.

Results

There is a strong association between either attachment or bone loss and stroke up to the age of 60 years (Fig. 1 and 2).

No association between either attachment or bone loss and stroke has been detected in participants older than 60 years of age (Fig. 1 and 2).

The association between gingivitis and stroke was weaker in participants older than 60 but remained statistically significant (Fig. 3).
Fig. 1 Multivariate logistic regression model for the association between attachment loss and stroke in subjects older than 60 or up to 60 years of age. Odds ratios and 95%-confidence intervals are listed.

Fig. 2 Same multivariate logistic regression model as in fig. 1 for the association between the relative radiographic bone loss and stroke in subjects older than 60 or up to 60 years of age.

Fig. 3 Same multivariate logistic regression model as in fig. 1 for the association between gingivitis and stroke in subjects older than 60 or up to 60 years of age.

Discussion and Conclusions

Associations between chronic periodontitis and cerebrovascular disease seem to be detectable in younger patients, only. This study was funded by the Deutsche Forschungsgemeinschaft (German Research Council, Grant # Gr1102/3-1).

Aim: To investigate the influence of the age of study population on the association between periodontitis and ischemic stroke.

Material and Methods:
Cross-sectional study with periodontitis (CPT) and CVD risk factors in 500 patients aged 40-60 years.

Results:
There is a strong association between periodontitis and stroke in patients aged 40-60 years. The association between periodontitis and stroke was stronger in patients aged 50-60 years compared to those aged 40-50 years.

Conclusions:
Periodontitis is an independent risk factor for ischemic stroke in patients aged 40-60 years. The association between periodontitis and stroke was stronger in patients aged 50-60 years compared to those aged 40-50 years.
